Bug Fixes

No	Functions	Fixes
1	Downlink synchronization	If you keep the file open on the client side, deleting it on the server side leaves the file on the client side undeleted
2	Downlink synchronization	If the computer is restarted during synchronization, the synchronization may not be completed normally and the subsequent downstream synchronization may not work.
3	Downlink synchronization	Files with extension json are not synced
4	Downlink synchronization	When updating files recovered from the trash on the server side, some sync files may be deleted by Fleekdrive desktop.
5	Downlink synchronization	If a file that does not have version information locally is updated on the server side, an error will occur during downlink synchronization and the clean process will be automatically executed.
6	Uplink synchronization	After executing the clean process, some files may be deleted and synchronized even though the user has not actually deleted them.
7	Bidirectional synchronization	If the file is deleted locally or from the server before the file rename on the server side is down synced, an error will occur in the error processing of down sync and the clean process will be executed.
